TEXT DATA IS CLEAN

DATA CLEANING:

LABEL ENCODING:

QUESTIONS AND ANSWERS:

1. What are the most common words used by people who have taken the airline 'United'?

Here,we are using freqdist to use frequency for finding the most common word from the tokenized words in the sentence. We remove stopwords and special characters before finding the word.

2. What is the most common usertimezone who have taken the airine 'Virgin America'?

Here,we are going through the rows of only the people who have taken the airine Virgin America and finding the most common user timezone in those rows

TfidfVectorizer and hstack:

TfidfVectorizer:

Convert a collection of raw documents to a matrix of TF-IDF features.

hstack:

Here, HSTACK is used to make the sparse matrix (array) and the other columns into a single array for machine learning, fitting and calculating accuracy.

In CountVectorizer we only count the number of times a word appears in the document which results in biasing in favour of most frequent words. this ends up in ignoring rare words which could have helped is in processing our data more efficiently.

To overcome this, we use TfidfVectorizer.

In TfidfVectorizer we consider overall document weightage of a word. It helps us in dealing with most frequent words. Using it we can penalize them. TfidfVectorizer weights the word counts by a measure of how often they appear in the documents.

```
In [35]: M X=hstack([tweet_df1[['tweet_id','airline_sentiment_confidence','airline']],X_tfidf])
```

HERE, WE USE HSTACK TO COMBINE TEXT COLUMN AND OTHER COLUMNS AS OUR INDEPENDENT VARIABLES.

DECISION TREE CLASSIFIER:

NAIVE BAYES:

RANDOM FOREST CLASSIFIER:

ENSEMBLE MACHINE LEARNING MODELLING:

Ensemble learning is a machine learning paradigm where multiple models (often called "weak learners") are trained to solve the same problem and combined to get better results. The main hypothesis is that when weak models are correctly combined we can obtain more accurate and/or robust models.

Some ensemble methods are:

RANDOM FOREST (as shown above)

BAGGING

BOOSTING

BAGGING:

A **Bagging classifier** is an ensemble meta-estimator that fits base classifiers each on random subsets of the original dataset and then aggregate their individual predictions (either by voting or by averaging) to form a final prediction. Such a meta-estimator can typically be used as a way to reduce the variance of a black-box estimator (e.g., a decision tree), by introducing randomization into its construction procedure and then making an ensemble out of it.

BOOSTING:

Boosting is an ensemble modeling technique which attempts to build a strong classifier from the number of weak classifiers. It is done building a model by using weak models in series. Firstly, a model is built from the training data. Then the second model is built which tries to correct the errors present in the first model. This procedure is continued and models are added until either the complete training data set is predicted correctly or the maximum number of models are added.

SUMMARY:

We are using various classification algorithms to find accuracy scores and observe which algorithm gives the best accuracy score. We add the text column also as our independent variable through the help of TfidfVectorizer Which converts text into a sparse matrix which is helpful in machine learning.

RANDOM FOREST ALGORITHM suits the best for the **given dataset**. **BOOSTING** has increased its accuracy score a little higher.

ENSEMBLE MODELLING is a process where multiple diverse models are created to predict an outcome, either by using many different modeling algorithms or using different training data sets.

The ensemble model then aggregates the prediction of each base model and results in once final prediction for the unseen data.

The motivation for using ensemble models is to reduce the generalization error of the prediction. As long as the base models are diverse and independent, the prediction error of the model decreases when the ensemble approach is used.
